

PATENT APPLICATION

Docket No.: D427a

Inventor: Mr. Bartlett Scott Hudson Michel

Title: Cooperative Adaptive Web Caching Routing and Forwarding Web  
Content Data Broadcasting Method

SPECIFICATION

Statement of Government Interest

The invention was made with Government support under contract  
No. F04701-93-C-0094 by the Department of the Air Force. The  
Government has certain rights in the invention.

## Background of the Invention

Web caching is generally recognized as an important service for alleviating focused overloads when certain web content data stored on a web server become popular. A user will have a user internet protocol address (IPA) and will select a uniform resource locator (URL) identifying the sought after web content data and the corresponding web server storing the web content data. The user makes use of the domain name system (DNS) and is provided with a DNS server IPA. The DNS system cross references a web server name, contained in a URL, to the corresponding destination web server IPA. The web server name and user IPA are transmitted to a DNS server at the DNS IPA. The DNS server then returns to the user at the user IPA the destination IPA of the web server storing the sought after URL web content data. The user then transmits the user IPA, the destination IPA and URL as a hypertext transport protocol (HTTP) protocol message into the internet where the http message is routed and forwarded through internet routers to the web server at the destination IPA where the web server then returns to the user at the user IPA the requested URL web content data. Web caching introduces a web content data cache store proximal to the user to reduce retrieval time latency of sought after URL web content data.

A web caching system consists of one or more caches that store copies of web pages, images and other web content data with the expectation that the stored copies will be repeatedly requested. A purpose of the web caching system is to reduce both the number of requests received by a web server where the desired content data is

1 located, while providing a faster web interaction experience for  
2 the user. The web caching system reacts and adapts to user browsing  
3 behavior. Hot spots develop from time to time when user browsing  
4 behavior creates network congestion in the internet topological  
5 vicinity of and sustained workload at a particular web server. The  
6 JPL Mars Pathfinder landing, the Starr Report, and downloads of  
7 updated Netscape Communicator, a trademark of Netscape, and  
8 Internet Explorer, a trademark of Microsoft, browsers are several  
9 examples of activity that previously generated internet wide hot  
10 spot events. A more recent phenomenon are short lived hot spots  
11 caused by the traffic generated by portal sites, typically news and  
12 sports services, where the web content data is periodically changed  
13 and updated during the course of the day causing users to  
14 periodically refresh their copy of the web content data.

15  
16 Web caching systems may be designed as stand alone or  
17 cooperative systems. The difference between these two types of  
18 caching systems is whether or not a cache interacts with another  
19 cache while processing a user's request. Each user request for web  
20 content data is identified using the URL. When a proximal stand  
21 alone cache receives a user request, the proximal stand alone cache  
22 checks whether or not the URL web content data is locally stored,  
23 either in the proximal stand alone cache memory and disk storage  
24 devices. If the URL web content data is locally stored by the stand  
25 alone cache, the URL web content data is immediately sent back to  
26 the requesting user. Otherwise, the proximal stand alone cache  
27 fetches the URL web content data directly from the designated web  
28 server.

1  
2 A cooperative caching system, by contrast, is a system where  
3 web caches interact with each other in order to share stored web  
4 content data. When a proximal cooperative cache receives a user  
5 request, the proximal cache also checks whether or not the URL web  
6 content data was previously and locally stored. Again, if the  
7 proximal cooperative cache has stored the URL web content data, the  
8 URL web content data is sent to the requesting user. If the URL web  
9 content data is available from another distal cooperative cache,  
10 the proximal cache sends the user request to the distal cooperative  
11 cache. Otherwise, the proximal cache fetches the URL web content  
12 data from the designated web server.

13  
14 The Squid web caching system is an example of a cooperative  
15 web caching system. In the Squid system, caches are grouped  
16 together in peer hierarchical groups, where the peer groups have a  
17 parent and child relationship with each other. A proximal cache in  
18 the Squid web caching system first checks to see if a user  
19 requested URL web content data is stored locally. If the URL web  
20 content data is not locally stored by the proximal cache, the  
21 proximal cache sends the request to all caches in the proximal  
22 cache peer group. If the proximal sending cache does not receive a  
23 reply from any cache in the peer group, the proximal cache sends  
24 the user request to a distal cache in the parent peer group. The  
25 process of checking whether the URL web content data is locally  
26 stored, querying the other caches in the peer group, and  
27 subsequently sending the user request to the next parent peer group  
28 repeats when the URL web content data is not stored by the cache or

1 any of the caches in the peer group. The process stops when a root  
2 peer group is encountered, that is, a peer group that does not have  
3 a parent peer group. A cache in the root peer group also checks  
4 whether the requested URL content data is locally stored, and if  
5 not, the cache in the root peer group fetches the requested URL  
6 content data directly from the web server named in the URL. The URL  
7 web content data is stored by the root peer group cache and sent  
8 from the root peer group cache back to the cache that relayed the  
9 user request to the root peer group. The URL web content data is  
10 subsequently stored and propagated down through the caches in the  
11 peer groups through which the user request was relayed until the  
12 URL web content data reaches the proximal cache that originally  
13 received the request from the user, at which time, the proximal  
14 cache sends the URL web content data to the user. The disadvantage  
15 of this cooperative caching system is that the caches do not  
16 forward user requests between peer groups other than following the  
17 peer group hierarchy. These and other disadvantages are solved or  
18 reduced using the present invention.

## Summary of the Invention

An object of the invention is to provide a method for accessing requested web content data that is stored in a network of distributive caches and is identified by an uniform resource locator (URL).

Another object of the invention is to provide a method for accessing URL requested web content data stored in a network of distributive caches.

Yet another object of the invention is to provide a method for accessing URL requested web content data stored in distributed caches by application level routing and forwarding.

Still another object of the invention is to provide a method for accessing URL requested web content data using adaptive and cooperating web caching using forwarding tables for routing URL requests and internet protocol addresses (IPAs) between distributed web caches.

Still a further object of the invention is to provide a method for accessing URL requested web content data using adaptive and cooperating web caching using forwarding tables and URL wildcard characters for routing a collection of URL requests and internet protocol addresses (IPAs) between distributed web caches for accessing a respective set of web content data.

1 Yet a further object of the invention is to provide a method  
2 for expressing URLs as URL identifiers for adaptive and cooperative  
3 web caching.

4  
5 Still another object of the invention is to provide a method  
6 for expressing URLs as URL identifiers for adaptive and cooperative  
7 web caching using URL decomposition, URL wildcards, and URL  
8 compression.

9  
10 Yet another object of the invention is to provide a method for  
11 creating forwarding tables using encoding for representing URLs for  
12 forwarding URL requests to adaptive cooperative distributed web  
13 caches.

14  
15 Yet another object of the invention is to provide a method for  
16 creating forwarding tables using hash function encoding for  
17 representing URLs for forwarding URL requests to adaptive  
18 cooperative distributed web caches.

19  
20 A still further object of the invention is to provide a method  
21 for creating forwarding tables using a table data structure that  
22 decomposes URLs for cross referencing URLs to web cache IPAs for  
23 forwarding URL requests to adaptive cooperative distributed web  
24 caches.

25  
26 A still further object of the invention is to provide a method  
27 for creating forwarding tables using hash function encoding to  
28 address forwarding information in forwarding tables.

1  
2 Still a further object of the invention is to provide a method  
3 for communicating URLs, IPAs and relative web hop distances between  
4 distributed web caches storing sought after web content data using  
5 an application level routing protocol containing a forwarding list  
6 of URLs, IPAs and web cache distance metrics for adaptively  
7 maintaining forwarding tables for forwarding and relaying URL  
8 requests to the distributed web caches that locally store requested  
9 web content data.  
10

11 Yet another object of the invention is to provide a method for  
12 broadcasting URLs, IPAs and relative web hop distances between  
13 distributive web caches storing sought after web content data using  
14 an application level routing protocol containing a routing protocol  
15 forwarding list of URLs, IPAs and web cache distance metrics for  
16 adaptively maintaining forwarding tables for forwarding URL  
17 requests to the distributed web caches that locally store the  
18 requested web content data for replicating web content data in a  
19 plurality of adaptive cooperating distributed web caches.  
20

21 The invention is directed to an adaptive and cooperative web  
22 caching method that is an application level routing and forwarding  
23 method used to achieve efficient access, forwarding and location of  
24 replicated web content data using a web caching system comprising a  
25 plurality of adaptive and cooperating distributive web caches. The  
26 adaptive and cooperative web caching method is suitable for  
27 reducing retrieval delays of sought after web content data in  
28 response to web user requests. This web retrieval delay, or

1 latency, is reduced by the rapid determination of cache IPAs cross  
2 referenced to URLs in each adaptive forwarding table of the  
3 adaptive and cooperative web caches.

4  
5 A request receiving proximal cache receives user web requests  
6 from a user's browser or other web access device that was  
7 previously configured or directed to communicate with the proximal  
8 receiving cache instead of directly retrieving web content data  
9 from the web server identified by a URL contained in the user web  
10 request. A request receiving proximal cache operates as a stand  
11 alone cache when receiving a user request containing a URL and then  
12 determining whether the URL web content data is stored locally  
13 within the cache. When the user requested URL web content data is  
14 stored locally within the proximal cache, the URL web content data  
15 is immediately communicated back to the user. In directly  
16 responding to user requests, the proximal web cache functions as  
17 does a conventional stand alone web cache.

18  
19 The proximal web cache however also maintains a forwarding  
20 table for cross referencing URL and IPAs for locating distal  
21 cooperative web caches also storing the sought after web content  
22 data. When the URL of the sought after web content data is not  
23 cross referenced to an IPA in the proximal web cache, the proximal  
24 web cache continues to function as a stand alone cache and directly  
25 retrieves web content data referred to by the URL from the web  
26 server that originally and permanently stores the requested web  
27 content data by addressing the web server using the conventional  
28 domain name system (DNS) protocol that translates the web server

1 name into a web server IPA and by communicating with the web server  
2 IPA using the necessary transport and application protocols  
3 appropriate to the URL. Then the proximal web cache stores the web  
4 content data from a web server and the proximal web caches further  
5 continues to function as a stand alone cache. The forwarding table  
6 is not used when storing requested web content data from a web  
7 server as the proximal cache does not need a forwarding table to  
8 recognize those URLs that identify locally stored web content data.

10 In a first aspect of the invention, a web cache may  
11 additionally function to adaptively replicate requested web content  
12 data by storing web content data received from an associated distal  
13 web cache in response to frequent requests or anticipated user  
14 activity, thereby causing other distal adaptive and cooperative  
15 caches to update the respective forwarding tables of the distal  
16 caches so that future user requests for the requested web content  
17 data are retrieved directly from or routed through one or more  
18 intermediate adaptive and cooperative distal web caches to that  
19 distal web cache that distally but there locally stores the  
20 requested web content data. When the sought after web content data  
21 is not stored in the receiving proximal web cache, the proximal web  
22 cache uses the locally stored forwarding table to cross reference  
23 the URL to an IPA of a cooperative distal web cache that distally  
24 but there locally stores the requested web content data. When  
25 requested web content data is stored by an associated distal web  
26 cache, the forwarding table is then used by the receiving proximal  
27 cache to recognize those URLs having corresponding web content data  
28 stored in the distal web caches efficiently locating where users

1 requested web content data has been previously stored in a system  
2 of adaptive distributive cooperative web caches.

3  
4 In a second aspect of the invention, a proximal web cache may  
5 further function to broadcast routing information to cooperative  
6 distal web caches that can then adaptively update the distal but  
7 there locally stored forwarding tables of the receiving distal web  
8 caches to provide adaptive updates to the forwarding tables through  
9 the distributive web cache system for efficient subsequent routing  
10 of URL requests to other cooperative distal web caches in the  
11 application level network of adaptive and cooperative distributed  
12 web caches. The proximal web cache broadcasts in packets a routing  
13 protocol forwarding list defined by a routing protocol data  
14 structure. The routing protocol forwarding list contains URLs,  
15 IPAs, and metric distances data indicating where web content data  
16 is stored in the system of cooperative distributive web caches. The  
17 forwarding list IPAs are preferably locations of cooperative  
18 forwarding distal web caches that relay during web hops URL  
19 requests to a distal web cache storing the sought after URL web  
20 content data, but can be the locations of distal web caches or web  
21 servers storing the web content data.

22  
23 In the first two aspects, the invention is a method directed  
24 to the efficient location and accessing of web content data in an  
25 adaptive cooperative distributed web caching system using an  
26 application level web cache routing protocol. The routing protocol  
27 is used to exchange location information between cooperative web  
28 caches. The web cache routing protocol is defined by a routing

1 protocol data structure and communicated in a sequence of routing  
2 protocol packets exchanged between the cooperative web caches. The  
3 protocol data structure of the web cache routing protocol includes  
4 the IPA of the broadcasting proximal cache, the broadcast IPA  
5 corresponding to a group of one or more recipient cooperative  
6 distal caches, and includes the routing protocol forwarding list  
7 comprising URLs, respective distal content storing web cache IPAs  
8 and distance metrics. The URL and IPA respectively identify web  
9 content data and location of a storing web server or cooperative  
10 storing distal web cache. The distance metric indicates the number  
11 of web cache hops required to reach the storing web server or  
12 storing distal web cache from the proximal web cache receiving the  
13 forwarding list. As the routing protocol forwarding list is  
14 communicated through successive cooperative web caches, the  
15 distance metric is incremented so that the current value of the  
16 distance metric is equal to the number of required web cache hops  
17 from the current web cache receiving the forwarding list to the web  
18 cache or web server where the web content data associated with the  
19 respective URL in the forwarding list is stored, so that, each  
20 recipient, in turn, then knows the required number of web cache  
21 hops to the storing cooperative distal web cache or web server. The  
22 distance metric, and hence, the number of web cache hops, is  
23 incremented when traversing from one to another cache and between  
24 local groups of cooperative web caches, with the cooperative web  
25 caches being organized into interconnected and overlapping groups  
26 of web caches that define the network topology of the system of  
27 adaptive and cooperative web caches. A proximal cache may  
28 periodically send routing information to the distal caches in the

1 local groups in which the proximal cache is a member. A cache  
2 within one group can broadcast routing information to all other  
3 caches within the local group. A cooperative web cache can be a  
4 member of a plurality of local groups of caches to overlap the  
5 groups of cooperative caches for effectively communicating URL  
6 requests and web content data between the groups of caches. In this  
7 manner of overlapping groups of caches, routing information can  
8 propagate through one or more groups of cooperative web caches  
9 during web hops throughout the entire network of cooperative  
10 distributive web caches.

11  
12 A third aspect of the invention is the decomposition of exact  
13 and wildcard URLs into a sequence of URL components to efficiently  
14 represent a URL decomposition tree in the proximate web cache  
15 forwarding table. An exact URL is a character string composed of a  
16 scheme portion, a web server name portion, a path portion, and a  
17 type portion indicating a file format, in combination,  
18 corresponding to the web content data originally and permanently  
19 stored by a web server. The web server name portion in an exact URL  
20 that is further decomposed into name components reflecting a  
21 hierarchical naming convention defined by the conventional domain  
22 naming system (DNS). The path portion in an exact URL is further  
23 decomposed into one or more path components. Hence, a decomposed  
24 exact URL is a sequence of components consisting of a scheme  
25 component, name components, path components and a type component.  
26 The scheme portion typically includes only one scheme component.  
27 The type portion typically include only one type component. Hence,  
28 each URL portion comprises one or more URL components.

1  
2 A wildcard URL is a string composed of either a scheme, a web  
3 server name, and path terminated by a wildcard character or a  
4 scheme and a web server name containing a wildcard character. A  
5 wildcard character terminating the path of a wildcard URL  
6 represents a group of exact URLs and associated web content stored  
7 in a distal web cache or a web server. A wildcard character  
8 occurring in the web server name of a wildcard URL represents a  
9 group of web servers and the groups of exact URLs and associated  
10 web content data originally and permanently stored by the group of  
11 web servers. Hence, a decomposed wildcard URL is a sequence of URL  
12 components consisting of a scheme component, name components and  
13 optionally path components terminating with the wildcard component.  
14

15 A URL decomposition tree is a data structure that stores a  
16 collection of decomposed exact and wildcard URL components that  
17 preserves the sequential ordering of decomposed exact and wildcard  
18 URL components. The decomposition tree serves to reduce unnecessary  
19 duplication of decomposed exact and wildcard URL components already  
20 stored in the URL decomposition tree. The proximal cache forwarding  
21 table stores a URL decomposition tree by inserting the URL  
22 components from decomposed URLs contained in the forwarding table.  
23 The forwarding table links decomposed URL components to the  
24 preceding decomposed URL components to form a complete exact or  
25 wildcard URL. The first decomposed URL component, that is, the  
26 scheme component, is not linked to a preceding decomposed URL  
27 component. The final decomposed URL component, that is typically a  
28 wildcard component or a type component, in addition to being linked

1 to the preceding decomposed URL component, is linked to the IPA of  
2 the distal cache with the minimum web cache distance metric as  
3 learned from the web cache routing protocol.

4  
5 A fourth aspect of the invention is the use of URL encoding  
6 for effectively storing URL identifiers in the forwarding table.  
7 URL encoding is preferably hash function encoding used to  
8 efficiently store compressed URLs for identifying the URLs. Exact  
9 URLs, wildcard URLs, and compressed URLs are referred to herein  
10 collectively as URL identifiers. The URL identifiers serve to cross  
11 reference, that is, locate and access decomposed URLs. The  
12 compressed URL identifiers are cross referencing indices into the  
13 forwarding table and represent a decomposed URL with or without  
14 storing the URL components so as to effectively store the URL  
15 decomposition tree of linked decomposed URLs. The URL forwarding  
16 table is a representation of the URL decomposition tree for rapidly  
17 and efficiently determining the IPA of and metric distance to a web  
18 server or distal cache locally there storing the sought after web  
19 content data.

20  
21 In the preferred form, a decomposed URL is transformed into a  
22 sequence of hashing code values by a hashing function. A hashing  
23 function converts an input string of URL components into an output  
24 number within a finite range. The sequence of hashing codes indexes  
25 successive decomposed URL components in the proximal cache  
26 forwarding table for reducing the time required to search the  
27 proximal web cache forwarding table when determining the IPA and  
28 metric distance of the forwarding cache or the distal cache storing

1 the sought after web content data. The sequence of hash codes are  
2 used primarily to compress an exact or wildcard URL into a coded  
3 URL identifier and secondly to locate the decomposed URL in the URL  
4 decomposition tree in the forwarding table. The forwarding table  
5 can then be efficiently used for locating the IPA and metric  
6 distance of a distal cache storing sought after web content data,  
7 and also used for efficiently generating the routing protocol  
8 forwarding list during broadcasting.

9  
10 The adaptive web caching method of the present invention  
11 efficiently expresses the URLs as URL identifiers referring to web  
12 content data stored in an adaptive and cooperative web caching  
13 system by URL decomposition, wildcard truncation, and URL  
14 compression methods. These methods provide application level web  
15 cache routing protocols to maintain cooperative web cache  
16 forwarding tables in order to direct URL requests to identified web  
17 caches and servers for accessing or replicating web content data.  
18 The adaptive cooperative web caching method provides for the access  
19 of requested web content data from any of the cooperative web  
20 caches, provides for the broadcasting of routing information for  
21 adaptively updating forwarding tables, provides for the forwarding  
22 of URL requests to cooperative caches using a forwarding table of  
23 decomposed URLs cross referenced to IPAs, and provides for the  
24 encoding and compression of exact and wildcard URLs into compressed  
25 URLs for rapid cross referencing of a requested URL to web server  
26 or web cache IPA for reducing web content data retrieval latency  
27 times. These and other advantages will become more apparent from  
28 the following detailed description of the preferred embodiment.

## Brief Description of the Drawings

Figure 1 is a block diagram of a user cache and web server network depicting web caches in the internet.

Figure 2 is a diagram of an application level network.

Figure 3 is a diagram of a uniform resource locator (URL) decomposition tree.

Figure 4A is a hash code value table of a hash code sequence generated by from an exact URL.

Figure 4B is a hash code value table of a hash code sequence generated by from a wildcard URL.

Figure 5 is a diagram of a URL forwarding table.

Figure 6a is a diagram of a routing protocol data structure.

Figure 6b is a diagram of a routing protocol message sequence.

Figure 7 is a flow diagram of the web content caching application level routing and forwarding process.

///

## Detailed Description of the Preferred Embodiment

An embodiment of the invention is described with reference to the figures using reference designations as shown in the figures. Referring to Figure 1, users 10a, 10b, 10c and 10d collectively referred to simply as users or user, caches 12a, 12b, 12c, 12d, 12e and 12f, collectively referred to simply as caches or a cache, routers 14a, 14b, 14c, 14d, 14e, 14f, 14g, 14h, 14i, 14j, and 14k, collectively referred to simply as routers or a router, and web servers such www.aero.org 16a and www.uspto.gov 16b, collectively referred to simply as servers or a server, are generally accessible on the internet represented as interconnecting lines extending between the users, caches, routers and servers. The web is a collection of web servers that utilize a hypertext transport protocol (http) for accessing web content data stored on the web servers. The internet is an interconnecting medium through which http requests and web content data are communicated between users and web servers. Users, routers, caches and servers have a unique internet protocol address (IPA) typically assigned from a block of consecutive IPAs provided by an internet provider service (IPS). A router is a device that directs data packets between users, caches and servers based on source and destination IPAs in each data packet. A user can enter a uniform resource locator (URL) for addressing and accessing a server by entering the URL into a locally operating browser, such as Internet Explorer ® a trademark of Microsoft Corporation and Netscape Communicator ® a trademark of Netscape Corporation. The uniform resource locator (URL) is a web address that identifies a web server and respective server web

1 content data. A URL is a request located within an http protocol  
2 message. The http message with the URL and web content data are  
3 segmented into one or more data packets during communication  
4 through the routers on the internet where each data packet contains  
5 both source and destination IPAs that identify the source and  
6 destination of communicated data packets. A web server stores  
7 respectively web content data that is addressed by a respective  
8 URL. The server is identified by a unique IPA and the particularly  
9 sought after web content data is identified by a respective URL.  
10 Hence, the URLs of a server are related by the IPA of the server.

11  
12 The URL is segmented into a scheme component, name components,  
13 a path components and a type component. The scheme component  
14 identifies the protocol such as hypertext transport protocol (http)  
15 or file transport protocol (ftp) used to transfer the sought after  
16 web content from the server to the user. The name components  
17 identifies the server and corresponds to a respective IPA. The path  
18 components identify the particular sought after server content  
19 data. The type component identifies the format type of web content  
20 data.

21  
22 A web cache functions to locally store within the cache a  
23 plurality of web content data of a respective plurality of URLs.  
24 The routers can route http protocol messages to a localized web  
25 cache for access to locally stored web content data without having  
26 to route the http protocol message through multiple routers to the  
27 identified web servers that permanently stores the respectively URL  
28 addressed web content data. Hence, the web caches serve as

1 intermediate web content data stores for the efficient access of  
2 web content data identified by the URL requests in the http  
3 messages.

4  
5 Referring to Figures 1 and 2, web caches 12 may be  
6 cooperatively grouped into cache groups, such as, cache group A  
7 18a, cache group B 18b, cache group C 18c, and cache group D 18d,  
8 collectively referred to as cache groups. Each of the cache groups  
9 contains one or more cooperative caches. Each of the cooperative  
10 caches can be assigned to one or more cache groups. The cache  
11 groups can be configured to be overlapping in that a particular  
12 cooperative cache, such as the C-D cache 12e, can be assigned to  
13 two cache groups, such as the cache group C 18c and the cache group  
14 D 18d. As such, an application level network can be flexibly  
15 configured in a variety of cache grouping structures, an example of  
16 which is shown in Figure 2. The cache grouping structure enables  
17 communication with cooperating distal caches in overlapping cache  
18 groups, but not with stand alone caches that operate independently  
19 of other caches, such as independent cache 12c. Hence, the grouped  
20 caches are cooperating caches within assigned cache groups.  
21 Cooperating caches within a cache group can locally store web  
22 server content data or access web server content information from  
23 another cooperating cache within the cache group. By overlapping  
24 cache groups, a cache from one group can access web content data  
25 from a cache in another cache group through overlapping cache group  
26 topography by relaying requests through one or more caches  
27 connecting cache groups together and between the caches within the  
28

1 same group, effectively relaying the URL requests between all  
2 caches within overlapped cache groups.

3  
4 When a grouped cache receives a request for locally stored web  
5 content data, the grouped cache transmits the web content data back  
6 to the requesting user or locally grouped cache. When a grouped  
7 cache receives a request for web content data that is not stored  
8 locally, the grouped cache relays the request to a distal cache  
9 within the local group of caches, which the distal cache may  
10 further function as a forwarding cache to relay the URL request to  
11 yet another distal cache, and in so doing, the request may  
12 propagate through a plurality of overlapping cache groups until the  
13 request is received by a cache storing locally the requested web  
14 content data. In the event that no cache within the overlapping  
15 cache groups stores the requested web content data, the receiving  
16 cache communicates the requests directly to the web server  
17 permanently storing the requested web content data.

18  
19 Referring to Figures 1, 2 and 3, and more particularly to  
20 Figure 3, in the preferred form, each cache stores the URLs  
21 corresponding to requests for respective web content data of the  
22 web servers using a URL decomposition tree. A URL is decomposed by  
23 the decomposition tree into the scheme, name, path and type URL  
24 portions having one or more components. The scheme portion has one  
25 scheme component that may be, for example, the http scheme 20. The  
26 name portion may have one or more name components, for example, www  
27 22c, aero 22b, and org 22a, or www 24c, uspto 24b, and gov 24a, or  
28 search 24d, uspto 24b, and gov 24a. The scheme component and name

1 components are separated by a :// delimiter character string. The  
2 name portion is typically partitioned into several name components.  
3 The name components are separated by delimiter periods and combined  
4 as a string of components to form a unique name, such as,  
5 www.aero.org, www.uspto.gov, or search.uspto.gov. Likewise, the  
6 path portion may also be partitioned into one or more path  
7 components such as CSTS 30a, CSRD 30b, index 30c, or CSTS 30a, CSRD  
8 30b, and index 30c, or CSTS 30a, CSRD 30b, and people 30d, or news  
9 32a and news 32b, or logo 34. The path components are separated by  
10 respective delimiter slashes. The type portion is typically only  
11 one type component, such as html 36a, html 36b, html 38a and gif  
12 40a and identifies the format type of the web content data. The  
13 scheme and type portions are typically not partitioned into smaller  
14 components. The file type component follows the last path component  
15 separated by another delimiter period. Exemplar URLs used in the  
16 Figure 3 of an exemplar URL decomposition tree include  
17 http://www.aero.org /CSTS/CSRD/index.html,  
18 http://www.aero.org/CSTS/CSRD/people.html,  
19 http://www.uspto.gov/news/news.html, and  
20 http://www.uspto.gov/logo.gif.

21  
22 The decomposition tree is in effect a hierarchical file name  
23 structure, the preferred form of which has the name components in  
24 reverse order but with the path components in forward order, even  
25 though forward, reverse or any arbitrary hierarchical component  
26 ordering could be used. In the preferred form, the org and gov, and  
27 like ending name components appear at the top of the name portions  
28 within the decomposition tree so that the decomposition tree

1 structures the file name by associated sets. Name grouping and path  
2 grouping into sets is perfected in the preferred form using a  
3 wildcard character, such as an asterisk. Hence, for each set of  
4 names, such as the gov 24a set of names, an \* asterisk extension 42  
5 is used to identify all names within the gov name set. Likewise,  
6 the URL name may be referenced to a plurality of files containing  
7 respective web content data that are addressed using a set of path  
8 components, all of which can be identified as a set using the \*  
9 wildcard. In the exemplar form, a \* wildcard 44 is used to  
10 reference all files in the www.aero.org set of files, including the  
11 CSTS/CSRD/index.html and CSTS/CSRD/people.html files, and another \*  
12 wildcard 46, for example, is used to identify all files within the  
13 search.uspto.gov name. In this manner, the decomposition tree can  
14 identify an individual URL or sets of URLs.

15  
16 Referring to Figures 1, 2, 3, 4a and 4b, more particularly to  
17 Figure 4a, in the preferred form, a decomposed URL may be encoded  
18 by transformation into a numerical value using a hashing function.  
19 A hashing function transforms and maps an input string into a  
20 numerical value within a predetermined mathematical range. The  
21 input string may be structured as characters or as an arbitrarily  
22 long sequence of bits. In the preferred form, the input string is a  
23 sequence of concatenated successive URL components, including or  
24 excluding the delimiters. In the preferred from, only the last  
25 delimiter between the last path component and the file type  
26 component is used while the remaining delimiters are ignored during  
27 hash encoding. Each sequence of concatenated successive URL  
28 components comprises a URL segment. In the preferred form, the

1 first hash code h1 is generated by applying the hashing function to  
2 the first URL component, that is, the scheme component, such as the  
3 http string of characters, as a minimal first URL segment. The  
4 second hash code h2 is generated by applying the hashing function  
5 to the first two URL components as successive concatenated strings,  
6 that is, the httporg string, without the :// delimiter, as a second  
7 hashed URL segment. The third hash code h3 is generated by applying  
8 the hashing function to the concatenation of the first three URL  
9 components as a string consisting httporgaero, without the :// and  
10 period delimiters resulting in the concatenation of the first three  
11 URL components http, org, and aero as a third hashed URL segment.  
12 The fourth hash code h4 is generated by applying the hashing  
13 function to the first four URL components http, org, aero and www  
14 as a concatenated string httporgaerowww, without the delimiters as  
15 yet a forth hashed URL segment. The fifth hash code h5 is generated  
16 by applying the hashing function to the first five URL components  
17 http, org, aero, www, and CSTS as a concatenated string of  
18 httporgaerowwwCSTS, without the delimiters as still a fifth hashed  
19 URL segment. The sixth hash code h6 is generated by applying the  
20 hashing function to the first six URL components http, org, aero,  
21 www, CSTS and CSRD as a concatenated string httporgaerowwwCSTSCSRD  
22 without the delimiters as a sixth hashed URL segment. The seventh  
23 hash code h7 is generated by applying the hashing function to the  
24 first eight URL components http, org, aero, www, CSTS, CSRD,  
25 people, and html as a concatenated string  
26 httporgaerowwwCSTSCSRDpeople.html as the final seventh hash URL  
27 segment covering the entire URL. Each concatenated URL segment may  
28 include delimiters, a preceding segment of URL components, and one

1 or more additional URL components. Each hashed URL segment consists  
2 of one or more URL components and has a respective hash code. In  
3 the preferred form, the file type component of a URL, such as the  
4 .html component, including the period delimiter, is juxtaposed with  
5 the last path components of the URL, such as the people path  
6 component, including the period delimiter. The use of delimiters  
7 in the hashed segment and a juxtaposition of the plurality of URL  
8 components can vary in different forms of the invention, so long as  
9 the URL is broken down into a plurality of components for compiling  
10 the decomposition tree preferably with successive respective  
11 hashing codes generated for each URL concatenated segment. In the  
12 preferred form, for example, only the last one of the delimiters is  
13 used, and only the last path component and file type component are  
14 juxtaposed during the last hashing process to generate the last  
15 entry in the hashing table comprising a list of hash codes for  
16 respective concatenated URL segments.

17  
18 The sequence of hash codes produced by successively  
19 concatenating decomposed URL components and delimiters and  
20 successively applying the hashing function are collectively an  
21 incremental URL hash code sequence. Hence, the sequence of hash  
22 codes h1, h2, h3, h4, h5, h6, and h7 represents an incremental URL  
23 hash code sequence as a URL identifier produced by decomposing the  
24 URL `http://www.aero.org/CSTS/CSRD/people.html` into the components  
25 `http`, `org`, `aero`, `www`, `CSTS`, `CSRD`, and `people.html`. Similarly,  
26 Figure 4B enumerates the incremental URL hash code sequence h1, h2,  
27 h3, h4, and h8 produced by successively applying the hash function  
28 to the concatenated components ending with the \* wildcard, such as

1 the URL http://www.aero.org/\*, including http, org, aero, www, and  
2 \* components.

3  
4 As shown in Figure 4A and Figure 4B, the hash function will  
5 always generate the same values, h1, h2, h3 and h4 for the first  
6 four decomposed URL components, http, org, aero, and www. The last  
7 hashing code h8 is generated from hashing the complete URL with the  
8 \* wildcard as a final URL hash segment. A hashing function can  
9 produce the same numerical code values for different input strings,  
10 but will always produce the same sequence of numerical values for a  
11 given decomposed URL with the identical URL components. Hashing  
12 codes are used for addressing URL segments cross referenced to  
13 routing data and for reducing the storage requirements in order to  
14 maintain all possible cross references for all URL segments created  
15 by decomposing a plurality of URLs. The storage reduction benefit  
16 exceeds the cost for resolving, in rare cases, differing URLs  
17 having an identical hashing code sequence.

18  
19 Referring to Figures 1 through 5, and more particularly to  
20 Figure 5, a URL forwarding table is used to translate received web  
21 request URLs into IPAs for forwarding web requests to the  
22 cooperative caches storing the requested web content data. The  
23 series of hashing codes 50 is a list of hash codes that are used as  
24 indices in the forwarding table. The series of hashing codes 50 are  
25 hashed values of at least one decomposed URL and respective URL  
26 segments. The series of hashing codes 50 are used for rapidly  
27 jumping from a present to successor URL component as the forwarding  
28 table is searched to match the longest initial sequence or prefix

1 of URL components previously stored in the forwarding table to the  
2 URL components from the decomposed received web request URL. A  
3 pointer list 52 having URL pointers, such as URL pointer 52a, is  
4 referenced by the respective hashing codes 50. Each of the URL  
5 pointers 52, such as URL pointer 52a, points to one or more URL  
6 data segments, such as URL data segment 54a of the URL data segment  
7 list 54. Each URL data segment, such as the URL data segment 54a,  
8 is defined by a URL data segment structure. In the preferred form,  
9 the URL data segment structure comprises a URL component field, a  
10 parent pointer and an IPA pointer field. The URL component field  
11 indicates a present URL component of a last component of a  
12 concatenated URL segment from a decomposed URL stored in the  
13 forwarding table. The parent URL pointer field stores a pointer to  
14 a parent URL data segment corresponding to a parent URL component.  
15 The parent URL pointer points to that URL data segment of the URL  
16 component immediately preceding the present URL component of the  
17 decomposed URL having a plurality of URL components. The URL data  
18 segment structure association of the present URL components and the  
19 parent URL components enable the linking of decomposed URL  
20 components into the complete URL. That is, the parent pointers  
21 serve to link present URL components with parent URL components so  
22 that all of the parent pointers of a URL data segment list link all  
23 of the URL component data segments in URL data segment list such as  
24 URL segment list 54 of a respectively decomposed URL so that the  
25 entire URL can be reconstructed through parental pointer linkage.  
26 The linked URL data segments are mapped to respective URL pointers  
27 and to respective hashing codes so that the list of hash codes 50  
28 can point to one or more URLs of the URL data segment list 54.

1 Exemplar URL segment list 54 contains two URLs, one being an exact  
2 URL `http://www.aero.org/CSTS/CSRD/people.html`, and the other being  
3 a wildcard URL `http://www.aero.org/*`. Each of the pointers 52 point  
4 to one or more URL data segments in the URL data segment lists. For  
5 example, URL pointer 52a points to URL data segment 54a and 56a in  
6 respective URL data segment lists 54 and 56, as well as other data  
7 segment lists such as data segment list 57. Each hash code  
8 represents a hashing of a URL segment comprising one or more linked  
9 URL components. Each hash code is computed for a respective URL  
10 segment with the hashed URL segment generating a respective hash  
11 code, URL pointer and present URL component. Only the first URL  
12 data segment does not have a parent URL component, and only the  
13 last URL data segment has an associated IPA pointer, so that, an  
14 entire URL from the first URL component to the last URL component  
15 can be formed by following the linked parental pointers between the  
16 first and last linked URL data segments with the reconstructed URL  
17 having an associated IPA pointer for locating in an IPA and  
18 distance metric list 58, the IPA location of a cooperative web  
19 cache or web server storing the web content data identified by the  
20 reconstructed URL. By way of example using the exact URL  
21 `http://www.aero.org/CSTS/CSRD/people.html`, the first http data  
22 segment would have no parental pointer, and the `people.html` last  
23 URL data segment would have an associated IPA pointer for pointing  
24 into an IPA and distance metrics list 58. In this exact URL  
25 example, the last two URL components and the last delimiter are  
26 grouped together during decomposition. By way of another example  
27 using the wildcard URL `http://www.aero.org/*`, the first http data  
28 segment also has no parental pointer, and the last wildcard

1 character \* data segment has an associated IPA pointer for pointing  
2 into the IPA and distance metric list 58 for locating the IPA of  
3 the web server or cooperative web cache distally storing the sought  
4 after set of web content data identified by the reconstructed  
5 wildcard URL stored in the forwarding table. The IPA and distance  
6 metric list 58 includes a list of IPAs and respective distance  
7 metrics that indicate the number of web cache hops from the  
8 proximal requesting web cache through any number of cooperative  
9 forwarding caches to that distal web cache or web server containing  
10 the URL identified web content data.

11  
12 Referring to Figures 1 through 6A, more particularly to Figure  
13 6A, a proximal web cache communicates URL network accessible data  
14 by broadcasting routing protocol packets comprising the source and  
15 destination IPAs 60 and a routing protocol forwarding list 59 to  
16 one or more distal caches located within the local cache group. A  
17 URL and the respective web content data is accessible by a proximal  
18 source web cache when either the proximal source web cache locally  
19 stores replicated web content data or the proximal source web cache  
20 received a routing protocol packet from a distal source web cache  
21 communicating URL accessible data, thereby identifying the URLs and  
22 respective web content data accessible by the proximal source web  
23 cache. The routing protocol packet contains a web cache source IPA  
24 and a web cache destination IPA 60 for communicating the routing  
25 protocol forwarding list 59. The web cache source IPA and a web  
26 cache destination IPA 60 are used by network routers to communicate  
27 the routing protocol packet from a web cache or web server  
28 identified by the source IPA to a distal web cache identified by

1 the destination IPA. Along with the source IPA and destination IPA  
2 60, the router transports the routing protocol forwarding list 59  
3 containing a list of routing line items each consisting of a URL  
4 identifier, such as URL 1, a distal web cache location, such as IPA  
5 1, of the proximal source cache that relays or stores locally the  
6 replicated web content data identified by the web content  
7 identifier, and a web cache distance metric, such as distance 1,  
8 indicating the distance in web cache hops between the broadcasting  
9 proximal source web cache and a distal web cache storing the web  
10 content data. When a source cache containing sought after web  
11 content data belongs to two or more different cache groups, this  
12 web content data is accessible by any web cache within these  
13 different cache groups by using the caches connecting overlapping  
14 cache groups as an intermediary communicating cache to interconnect  
15 the cache groups for communication between cache groups and  
16 consequently communicate with the source cache. Hence, the routing  
17 protocol forwarding list 59 indicates both replicated web content  
18 data stored locally by the broadcasting proximal source web cache  
19 and the replicated web content that may be retrieved via the  
20 proximal source web cache using the proximal source cache as an  
21 intermediary, such as when the proximal source web cache  
22 interconnects to two or more web cache groups and the sought after  
23 web content data is stored by a distal web cache in a distal web  
24 cache group relative to the distal caches in the proximal source  
25 cache group to which the broadcasted routing protocol is directed.  
26 The routing protocol forwarding list 59 is broadcasted to the  
27 distal web caches at the destination IPA and informs the distal web  
28 caches of what web content data is replicated and stored or may be

1 retrieved by the proximal source web cache. The routing protocol  
2 forwarding list 59 may contain multiple line item entries for the  
3 same URL identifier with different distal web cache locations,  
4 representing multiple paths through the interconnected web groups  
5 to the same or different distal web caches, enabling a proximal web  
6 cache to select that path with the lowest path distance metric. In  
7 the preferred form, the proximal source IPA in the forwarding list  
8 identifies the proximal source cache as a forwarding cache or as  
9 the distal cache storing the respective web content data.  
10 Alternatively, the routing packet source IPA can be used to  
11 identify the broadcasting proximal source cache such as when the  
12 source cache is a forwarding cache for web hops while the routing  
13 line item contains the distal IPA of the proximal or distal cache  
14 or web server storing the web content data.

15  
16 Referring to Figures 1 through 6B, more particularly to Figure  
17 6B, by way of example, the proximal A/D web cache 12d has  
18 previously stored locally the replicated web content data  
19 corresponding to URL identifiers URL 1 and URL 2, and creates  
20 routing protocol forwarding lists such as lists 59a and 59d, with  
21 two line item entries. The first line item entry contains URL 1,  
22 the originating A/D web cache IPA, and a web cache distance metric  
23 of 1. The distance metric of 1 indicates that the number of web  
24 cache hops from the currently receiving distal web cache, such as  
25 the -/A distal web cache 12a or the C/D distal web cache 12e, to  
26 the originating web cache, such as proximal web cache 12d, where  
27 the web content data is locally stored. The second entry contains  
28 URL 2, the originating web cache A/D IPA, and a web cache distance

metric of 1. The first two entries in the forwarding lists 59a and 59b indicate that web cache A/D 12d is the originating proximal web cache storing the URL referenced web content data, namely the web content data respectively referenced by URL 1 and URL 2. Web cache A-D 12d, a member of cache groups A and D, broadcasts two routing protocol data structure packets containing the IPAs 60a and 60d, and respective forwarding lists 59a and 59d to respective distal web cache 12a of cache group A and distal web cache 12e of cache groups C and D. With the first forwarding list 59d, the source IPA of the routing packet is the IPA of originating A/D web cache 12d and the destination IPA of the routing protocol packet is distal - /A web cache 12a. With the second forwarding list 59a, the source IPA of the routing protocol data structure packet is also the IPA of originating A/D web cache 12d and the destination IPA of the routing data structure packet is the IPA of the distal C/D web cache 12e. The difference between the two forwarding lists 59a and 59d from the originating web cache 12a is that the associated destination IPAs are different for routing and communicating the routing protocol forwarding list 59a and 59d to two different receiving distal web caches, such as distal web caches 12a and 12e.

Upon receiving the routing protocol packet, the recipient destination distal web cache such as the C/D cache 12e, broadcasts an updated forwarding list 59b with new line item entries, such as two additional to entries corresponding URL identifier URL 3, the IPA of cache C-D 12e, and a distance metric of 1, and corresponding to the web content data URL 4, the IPA of cache C-D 12e, also with a distance metric of 1 indicating the originating distance metric

1 of 1 for the locally stored web content data respectively  
2 referenced by URL 3 and URL 4. The new routing line items may also  
3 be inserted or updated with another web cache IPA and distance  
4 metric for indicating that the web content data referenced by the  
5 line item URL identifier is also stored in another web cache that  
6 may have a lower metric and is more proximal to the local web cache  
7 that is updating the forwarding list. Hence, the forwarding list  
8 59b of the routing protocol packet provides wide area linkage  
9 through which cooperating web caches communicate network accessible  
10 web content data for forwarding and routing of future web requests  
11 using URL identifiers, IPAs and distance metrics for referencing  
12 replicated web content data stored within the network of  
13 cooperative web caches.

14  
15 The forwarding list 59 of a broadcasted routing protocol data  
16 structure packet can increase in the number of line items when  
17 relayed from one web cache to another web cache as the routing  
18 protocol packet propagates through the network of cooperative web  
19 caches during broadcasting. For example, the web C/D cache 12e  
20 increments by one the web cache distance metric of the first two  
21 forwarding list entries received from cache A/D 12d such that the  
22 forwarding list entry corresponding to URL1 becomes distance 2 and  
23 the forwarding list entry corresponding to URL2 becomes distance 2,  
24 thereby indicating an increment of the web hop distance to the  
25 originating web cache 12d. A new and updated routing protocol  
26 packet containing the four entry forwarding list 59b is broadcasted  
27 with the source IPA of cache C/D 12e, and the destination IPA of  
28 B/C cache 12f. The updated routing protocol packet with forwarding

list 59b is broadcasted by the C/D cache 12e to the B/C cache 12f. Upon receiving the routing protocol packet from the C/D cache 12e, B/C cache 12f does not add any additional forwarding list entries in the shown example. However, the B/C cache 12f creates a new forwarding list 59 by copying the forwarding list received from cache C/D 12e, and increments the web cache distance metrics of the forwarding list 59c, that is, the distance metric corresponding to the forwarding list entry containing URL1 becomes distance 3, the distance metric corresponding to the forwarding list entry containing URL2 becomes distance 3, the distance metric corresponding to the forwarding list entry containing URL3 becomes distance 2, and the distance metric corresponding to the forwarding list entry containing URL4 becomes distance 2. The B/C cache 12f broadcasts the updated routing protocol packet to the -/B cache 12b with the updated forwarding list 59c, with the source IPA of the B/C cache 12f and the destination IPA of the B cache 12b of IPA data 60c. In this manner, routing protocol lists 59 can be updated and propagated through a hierarchy of network distributing grouped web caches for identifying network accessible web content data.

Broadcasting routing protocol packets and incrementing the web cache distance metric of each entry contained in the routing protocol forwarding list provides a recipient web cache with the exact and wildcard URL identifiers of web content stored by distal caches, the IPA of the proximal forwarding or distal cache, and a distance metric for indicating of how many web hops away the forwarding or distal web cache is from the distal web cache that locally stores the sought after web content data corresponding to

1 the URL identifier. Latency reduction is adaptively enabled by  
2 comparing the distance metrics received from multiple routing  
3 protocol packets received from multiple and differing web cache  
4 sources for a particular URL contained in the received forwarding  
5 list to the distance metric stored in the IPA and distance metric  
6 list 58 such that a recipient cache can update the IPA and distance  
7 metric list when the same URL is referenced to another web cache  
8 having the lower distance metric in web cache hops from the  
9 recipient web cache to the originating distal web cache storing the  
10 sought after web content. In this manner, URL request response  
11 times are adaptively reduced by maintaining the IPA and distance  
12 metric list 58 to have the minimum distance metric values for each  
13 of the respective IPAs in the list 58.

14  
15 The URL identifiers contained in a routing protocol data  
16 structure forwarding list may equivalently be expressed as either  
17 an exact URL, as a wildcard URL, or as an encoded URL such as a  
18 hash code in the preferred form using a sequence of hash codes for  
19 the respective concatenated URL segments. When communicated in a  
20 routing protocol packet, exact and wildcard URLs may be  
21 equivalently identified by a sequence of hash codes generated by  
22 the same hashing function used to insert URL data segment  
23 structures into a proximal cache forwarding table. URL hash codes  
24 are stored in a code list 50 in the proximal cache forwarding table  
25 for indexing the URL data segment lists 54, 56 and 57 for linkage  
26 determination through parental URL data segments to the last URL  
27 data segment pointing the IPA of a forwarding cache for web hops or  
28 a distal cache where the sought after web content data is distally

1 but there locally stored. However, the URL component field of the  
2 URL data segments may be left empty because the URL component is  
3 not known and cannot be reconstructed from the hash codes. Only the  
4 hash code is known as a URL identifier, but the URL data segments  
5 are still linked for determining if the URL web content data is  
6 accessible in the network of web caches. When a proximal cache  
7 looks up the requested URL in the forwarding table, the parent URL  
8 component fields enable the proximal cache to determine whether or  
9 not a given sequence of hash codes generated by a decomposed URL is  
10 present in the forwarding table, and consequently determine a  
11 forwarding cache IPA or distal cache IPA where the sought after web  
12 content data is located, even though the URL components in each URL  
13 data segment structure are unavailable. URL codes enable a  
14 compressed representation of exact and wildcard URLs, thereby  
15 reducing the size of the routing protocol packets communicated from  
16 a proximal source web cache to distal recipient web caches when the  
17 proximal source web cache broadcasts the routing protocol packets  
18 to the distal recipient cooperative web caches in the proximal web  
19 cache group.

20  
21 Referring to Figures 1 through 7, more particularly referring  
22 to Figure 7, a proximal web cache receives and classifies input  
23 packets 60. One type of input packet is the routing protocol data  
24 structure packet 62. Upon receiving and classifying an input packet  
25 60 as a routing protocol packet 62, the proximal cache examines the  
26 routing protocol forwarding list and examines each line item URL  
27 identifier to determine 64 whether the line item contains an exact  
28 or a wildcard 70 or a compressed URL 74 represented by URL codes.

1 If the URL identifier is an exact or wildcard URL, the proximal  
2 cache decomposes 70 the URL into linked data segments having URL  
3 components. If the URL identifier is a compressed URL, the proximal  
4 cache converts 74 the compressed URL into linked data segments  
5 where the URL components are empty place holders within a temporary  
6 list of linked URL data segments. The IPA field of last URL data  
7 segment structure from the decomposed or converted URL is updated  
8 72 with the IPA of the distal cache IPA contained in the current  
9 line item so as to complete the list of linked data segments. Then  
10 the temporary list of linked data segments is compared to the lists  
11 of linked data segments 54 in the forwarding table to determine 76  
12 whether the temporary list of linked data segments of the current  
13 line item are matched to a previously stored list of linked data  
14 segments 54. If the temporary list of linked data segments are  
15 matched 76, meaning the web content identifier of the current line  
16 item was previously stored in the forwarding table, then the  
17 distance metric of the current line item is compared 80 with the  
18 distance metric of the previously stored distance metric of the  
19 previously stored web content identifier to determine 80 whether  
20 the new distance metric is smaller, thereby indicating that a web  
21 cache storing the web content data referenced by the current line  
22 item web content identifier is closer in web cache hops than a web  
23 cache referenced by a previously stored web cache IPA. If matched  
24 76, and the previously stored web cache IPA is closer, that is, the  
25 previously stored distance metric is smaller 80 than the current  
26 line item distance metric, then the forwarding table and IPA and  
27 distance metrics table are not updated, and the proximal cache  
28 determines 85 if there are any more line items to be examined, and

1 if so, then the next line item 64 is processed, and if no more  
2 lines items are present 85, the web cache waits 60 for the next  
3 input packet. If the temporary list of linked data segments is not  
4 matched 76, meaning that the current line item represents newly  
5 stored web content data within the network of cooperative caches,  
6 the forwarding table is updated 82 with the new list of linked data  
7 segments and the IPA list 58 is also updated 84 with the new IPA  
8 and new respective distance metric. In the case of no match 76, the  
9 newly decomposed or converted linked data segments are added 82 to  
10 the forwarding table. If the temporary list of linked data segments  
11 is matched 76 and the new distance metric is smaller 80 in web hops  
12 for the web content identifier of the current line item, meaning  
13 the associated web content data of the current line item is closer  
14 with a smaller number of web hops through intermediate forwarding  
15 caches, the forwarding table is updated 82 with the temporary list  
16 of linked data segments and with a new IPA pointer, and the IPA  
17 pointer and metric list 58 is also updated 84 with the new IPA and  
18 new respective distance metric. In the case of a match 76 with a  
19 smaller distance metric, the list of linked data segments may be  
20 replaced with updated information such as with exact URL component  
21 data. When the forwarding table is updated 82 with additional or  
22 replacing linked data segment lists, then the IPA and distance  
23 metrics list 84 is also updated. In this manner, the forwarding  
24 table is updated with linked data segments of new line items having  
25 URL identifiers of web content data that has been newly stored  
26 within the group of cooperative web caches or has been stored in a  
27 web cache closer in fewer number of web hops to the proximal web  
28 cache than a more distal web cache previously storing the web

1 content data. After updating the forwarding table 82 and 84, the  
2 proximal cache determines 85 if there are any more next line items  
3 64, and if not waits 60 for the next input packet.

4  
5 Another type of packet that is received 60 is the user request  
6 packet 86. When the proximal cache receives a user request packet  
7 86, the proximal cache extracts 87 the exact URL from the user  
8 request packet. The proximal cache determines 88 whether the web  
9 content data identified by the exact URL extracted from the user  
10 request packet is locally stored 88, and if so, sends 89 the sought  
11 after web content data to the user and waits again 60 for the next  
12 input packet. If the web content data is not locally stored 88 by  
13 the proximal cache, the extracted exact URL from the user request  
14 packet is decomposed 90 into a list of data segments and encoded  
15 into a hash code sequence 91. The hash code values for the URL  
16 segments corresponding to the successive concatenated URL  
17 components are computed 91. The hash codes and data segments are  
18 examined 92 to determine if the hash code sequence and hence the  
19 URL data segments are matched 92. The proximal cache performs a  
20 lookup in the forwarding table to determine if a list of URL data  
21 segment structures corresponding to the respective URL code is  
22 stored in the forwarding table 92.

23  
24 If an exact match is found 92 in the forwarding table with a  
25 list of URL data segment structures with empty URL components  
26 acting as place holders representing the respective compressed URL,  
27 the proximal cache transmits 94 the original user request to the  
28 forwarding or distal cache referenced by IPA field of the last URL

1 data segment structure of the list of URL data segment structures  
2 of the respective compressed URL and again waits 60 for the next  
3 input packet. If the list of URL data segment structures  
4 corresponding to the URL components respectively corresponding to  
5 the extracted and decomposed exact URL is found 92 in the  
6 forwarding table, the proximal cache transmits 94 the original user  
7 request to the forwarding or distal cache IPA referenced by IPA  
8 field in the last URL data segment structure corresponding to the  
9 extracted and decomposed exact URL from the user request packet,  
10 and again waits 60 for the next packet.

11  
12 If an exact match with a list URL data segment structures  
13 corresponding to the respective URL code is not found 92, the  
14 proximal cache performs a wildcard lookup 93 in the forwarding  
15 table to determine if the list of URL data segment structures  
16 corresponding to the URL components matching the respective  
17 extracted and decomposed exact URL from the user request packet is  
18 present in the forwarding table. If the list of URL data segment  
19 structures corresponding to URL components from the extracted and  
20 decomposed exact URL is not present in the forwarding table, the  
21 last component in the list of URL components corresponding to the  
22 decomposed URL extracted from the http message is replaced with a  
23 wildcard character component, creating a wildcard URL from the  
24 original URL extracted from the user request packet with the last  
25 path component removed. The proximal cache again performs a  
26 wildcard lookup 93 in the forwarding table using the list of URL  
27 components corresponding to the wildcard URL. If the list of  
28 components corresponding to the wildcard URL is present 93 in the

1 proximal cache forwarding table, the proximal cache transmits 94  
2 the original user request to the forwarding or distal cache IPA  
3 referenced by the IPA field of last URL data segment structure  
4 corresponding to the respective wildcard component in the  
5 decomposed wildcard URL. The proximal cache transmits 94 the  
6 original user request to the forwarding or distal cache IPA  
7 referenced by IPA field in the last URL data segment structure  
8 corresponding to the extracted and decomposed exact URL from the  
9 user http message and again waits 60 for the next packet.

11 If the list of URL components corresponding to the decomposed  
12 wildcard URL is not present in the forwarding table, the parent URL  
13 component of the wildcard component is removed from the list of URL  
14 components and replaced by the wildcard component and the proximal  
15 cache performs another wildcard lookup 93 into the forwarding table  
16 for a shorter prefix list of URL components corresponding to the  
17 URL prefix of the current wildcard URL. If the shorter prefix list  
18 of URL components is present in the proximal cache forwarding  
19 table, the proximal cache transmits 94 the original request to the  
20 forwarding or distal cache IPA pointed to by the IPA field of the  
21 last URL data segment structure corresponding to the wildcard  
22 character component of the respective URL prefix and again waits 60  
23 for the next packet.

25 The proximal cache repeatedly removes 93 and replaces the last  
26 prefix parental component with the wildcard component so as to  
27 shift the wildcard component into the URL prefix of the URL  
28 component list and performs repeated lookups 93 until either the

1 successively shorter prefix wildcard URL is found present in the  
2 forwarding table for sending the URL request to a forwarding or  
3 distal cache 94, or until the list of URL components consists  
4 solely of a scheme component and the wildcard character component.  
5 If the list of URL components consists solely of the scheme  
6 component and the wildcard component, the wildcard set is not  
7 present, and the proximal cache sends 95 the original user request  
8 http message to the web server and then waits to receive 97 the web  
9 content data identified by the URL of the user request http  
10 message, and stores the web content data locally 97, and then  
11 transmits 89 the web content data to the user identified by the  
12 user request packet source IPA, and again waits 60 for the next  
13 input packet. In this manner, exact and wildcard URL identifiers  
14 found in the forwarding table are used to send user requests 94 to  
15 a forwarding cache or to a distal cache storing the sought after  
16 web content data, preferably transmitting through one or more  
17 intermediary forwarding caches interconnecting cache groups. There  
18 are many variations possible to the processing of received packets.  
19 For example, certain error messages may be communicated back to the  
20 user. The first URL component, that is, the scheme component, may  
21 be examined 92, and if the scheme is not recognized or supported by  
22 the proximal cache, the proximal cache may send an error indication  
23 packet 89 back to the requesting user and wait 60 for the next  
24 packet.

25  
26 As may now be apparent, the invention provides enhanced  
27 forwarding of URL requests and broadcasting of forwarding lists  
28 among web caches that function as a network of cooperating web

1 caches yet further simply function as stand alone caches. A request  
2 receiving proximal cache may operate as a conventional stand alone  
3 cache when receiving a user request from a user. When receiving a  
4 URL request, the proximal cache determines whether the sought after  
5 URL web content data is stored locally within the proximal cache.  
6 If the user requested URL web content data is stored locally within  
7 the proximal cache, the URL content data is communicated back to  
8 the user.

9  
10 The invention enhances web caching with URL request forwarding  
11 using a forwarding table and with routing list broadcasting  
12 preferably using the same forwarding table that preferably uses  
13 compressed URL identifiers and a decomposition tree for cross  
14 referencing the URL identifiers to forwarding and distal web cache  
15 IPAs. The proximal web cache contains a forwarding table for cross  
16 referencing URL to IPAs for locating cooperative distal web caches  
17 that store the sought after web content data. When the received URL  
18 request of the sought after web content data is not cross  
19 referenced to an IPA in the proximal web cache, the proximal web  
20 cache continues to function as a stand alone cache and directly  
21 retrieves web content data from the web server that originally and  
22 permanently stores the requested web content data by addressing the  
23 web server using the conventional domain name system (DNS) protocol  
24 that translates the web server name into a web server IPA. To  
25 communicate with the web server, the web cache is identified using  
26 the web cache IPA and communicates with the web server identified  
27 by the web server IPA using the necessary transport and application  
28 protocols appropriate for retrieving the web data content

1 identified by the respective URL. When the proximal web cache  
2 stores the web content data from the web server, the proximal web  
3 cache continues to function as a stand alone cache and the  
4 forwarding table of invention need not be updated when storing  
5 requested web content data from web server as forwarding the URL  
6 request is not needed as the web content data is now locally  
7 stored. However, for efficient broadcasting of the routing protocol  
8 list, the forwarding table data structure may also be used to keep  
9 track of locally stored web content data for the efficient  
10 generation of protocol routing lists having both proximal and  
11 distal web cache routing information.

12  
13 In a first aspect of the invention, the receiving proximal web  
14 cache functions to forward URL requests to cooperative distal  
15 caches that in turn provide the requesting user with the sought  
16 after web content data. The forwarding table is used by the  
17 proximal cache to recognize those URLs having corresponding web  
18 content data stored in the distal web caches. The user request  
19 receiving proximal web cache efficiently locates users requested  
20 web content data that has been previously stored in the cooperative  
21 distal web caches using the forwarding table cross referencing the  
22 URL request to the forwarding or distal cache IPA. When the sought  
23 after web content data is not stored in the proximal web cache, and  
24 when the requested URL is cross referenced to a forwarding or  
25 distal web cache IPA of a cooperative web cache, the proximal web  
26 cache communicates the URL request to the forwarding or distal web  
27 cache that distally but there locally stores the requested web  
28

1 content data. The distal web cache may then send the requested web  
2 content data directly to the requesting user.

3  
4 In response to a cooperatively routed URL request, the distal  
5 web cache can also send the requested web content data to the  
6 relaying proximal forwarding web cache as well. The forwarding  
7 table in the proximal web cache can further be used to keep track  
8 of proximately stored web content data when the proximal web cache  
9 adaptively replicates requested web content data received from a  
10 distal web cache in response to frequent requests or anticipated  
11 user activity. The proximal web cache can update the forwarding  
12 table accordingly with proximately stored web content data so that  
13 the forwarding table contains routing data indicating both  
14 proximately and distally stored web content data.

15  
16 In a second aspect of the invention, the proximal web cache  
17 may further function to broadcast routing information to  
18 cooperative forwarding and distal web caches that can then  
19 adaptively update the distal locally stored forwarding tables to  
20 provide adaptive updates throughout the distributed network of  
21 cooperative web caches for efficient subsequent routing of URL  
22 requests from cooperative proximal web caches to forwarding web  
23 caches and to distal web caches in the application level network of  
24 adaptive cooperative distributed web caches. A routing protocol is  
25 used to broadcast forwarding lists between the cooperative web  
26 caches. The forwarding list indicates the cooperative forwarding  
27 web caches or the distal web caches that store the web content data  
28 and indicates the URLs of the web content data. The web cache

1 routing protocol is defined by a routing protocol data structure. A  
2 sequence of protocol packets are exchanged between the cooperative  
3 web caches during broadcasting of the forwarding lists. The routing  
4 protocol includes the source IPA of the broadcasting proximal  
5 cache, the destination IPA corresponding to a one or more recipient  
6 cooperative web caches in a local group of web caches each of which  
7 may be assigned to one or more groups of caches for hierarchical  
8 routing. The routing protocol also includes the forwarding list  
9 comprising URL identifiers and respective cache distance metrics.  
10 The URLs and IPAs respectively identify the sought after web  
11 content data and the location of cooperative forwarding web caches  
12 or storing distal web caches. The distance metric indicates the  
13 number of required web cache hops from the proximal broadcasting  
14 web cache through forwarding web caches to the storing cooperative  
15 distal web cache for efficient URL request forwarding to the  
16 nearest distal web cache storing the sought after web content data.  
17 During broadcasting through intermediate cache hops, the distance  
18 metric is incremented so that the current value of the distance  
19 metric is equal to the number required web cache hops from the  
20 broadcasting cache so that each recipient cache can in turn  
21 determine the required number of hops to the storing cooperative  
22 distal web cache. The distance metric, and hence, the number of web  
23 cache hops, is incremented when traversing from one to another  
24 local group of cooperative web caches with the cooperative web  
25 caches being organized into overlapping groups of web caches that  
26 define the web caching topology. The web cache topology is created  
27 by the overlapping cache groups to enable caches to communicate  
28 throughout the network of distributed cooperative web caches. A

1 proximal cache may periodically broadcast routing information to  
2 the distal caches in the local cache groups in which the proximal  
3 cache is a member. A cache within one cache group can broadcast  
4 routing information to all other caches within the local cache  
5 group including those assigned to multiple cache groups for  
6 communication between groups of web caches. In this manner, routing  
7 information can propagate through the one or more groups of  
8 cooperative web caches throughout the entire network of cooperative  
9 web caches. Both URL request forwarding of the first aspect of the  
10 invention, and forwarding list broadcasting of the second aspect of  
11 the invention are directed to the efficient location of web content  
12 data in a network system of adaptive cooperative distributed web  
13 caches using an application level web cache routing protocol.

14  
15 A third aspect of the invention is the use of decomposition of  
16 exact and wildcard URLs into a sequence of URL components to  
17 efficiently represent a URL decomposition tree in the proximate web  
18 cache forwarding table. An exact URL is a character string that is  
19 decomposed into a sequence of linked URL components. The URL  
20 components reflect the hierarchical naming convention defined by  
21 the conventional domain naming system (DNS). A decomposed exact URL  
22 is a sequence of components consisting of a scheme, name, path, and  
23 file type components. A wildcard URL is a string composed of either  
24 the scheme, name, and path components terminated by a wildcard  
25 character or the scheme and name components terminated by a  
26 wildcard character. The decomposed wildcard URL is a sequence of  
27 URL components consisting of the scheme and name components and  
28 optionally path components terminating with the wildcard component.

1 A URL decomposition tree is formed by a plurality of URL data  
2 segment lists that store decomposed exact and wildcard URLs by URL  
3 components. The URL data segment lists preserve the sequential  
4 component ordering of decomposed exact and wildcard URL components.  
5 The forwarding table stores the URL decomposition tree by inserting  
6 the URL components within linked URL data segments of the lists of  
7 linked URL data segments that correspond to lists of linked URL  
8 components. A decomposed URL component is linked to the preceding  
9 decomposed URL component. The first decomposed URL component, that  
10 is, the scheme component, is not linked to a preceding decomposed  
11 URL component indicating the start of a decomposed URL. The final  
12 decomposed URL component is linked to the preceding decomposed URL  
13 component and is also linked to the IPA of the distal web cache and  
14 the web cache distance metric as might be indicated from a  
15 broadcasted routing protocol forwarding list. The decomposition  
16 tree of linked URL components with cross referenced forwarding or  
17 distal cache IPAs eliminates unnecessary duplication of decomposed  
18 exact and wildcard URL components already stored in the URL  
19 decomposition tree.

20  
21 A fourth aspect of the invention is the use of encoding and  
22 preferably hash function encoding as a compression method for  
23 accessing and storing decomposed URLs in the proximal cache  
24 forwarding table. The hash function is applied to successive  
25 concatenated strings of URL components organized as URL data  
26 segments each of which corresponds to one or more successive URL  
27 components. The URL data segments may further include URL  
28 delimiters. The hashing codes, data segment pointers, and URL data

1 segments are stored as lists in the forwarding table representing  
2 the URL decomposition tree. The sequence of hashing codes are used  
3 to compress the decomposed URL components into respective linked  
4 URL data segments each of which represents one or more linked URL  
5 components where the actual string of which may or may not be  
6 known. The URL forwarding table is a representation of the URL  
7 decomposition tree that can be used to rapidly and efficiently  
8 search for cross referenced IPAs of respective URLs using the  
9 hashing codes of the URLs to determine the IPA of a forwarding web  
10 cache or a distal web cache where the sought after web content data  
11 is locally stored. A decomposed URL is transformed into a sequence  
12 of hashing codes. The sequence of hashing codes indexing the  
13 pointers to successive respective decomposed linked URL data  
14 segments in the proximal cache forwarding table for reducing the  
15 time required to search the proximal web cache forwarding table to  
16 determine the IPA of the forwarding cache or distal cache where the  
17 sought after web content data is stored. When a URL is hashed into  
18 hashing codes and indexed to a complete decomposed URL by pointing  
19 to a respective linked series of URL data segments, the URL is  
20 found and hence cross referenced to the IPA and distance metric.  
21 The URL decomposition tree can be used for routing URL requests to  
22 distal web caches and can also be used to generate a routing  
23 protocol forwarding list during broadcasting.

24  
25 The URL identifiers can be either actual URLs or encoded  
26 versions of the URLs, such as hashing code versions. When a  
27 sequence of hashing codes is received by a proximal cache, the  
28 sequence of hashing codes and a respective sequence of pointers are

1 used to reference respective lists of URL data segments having  
2 parent pointers that function to link the URL data segments  
3 together for effectively linking together URL components that may  
4 or may not be present. When the sequence of received hashing codes  
5 are referenced through the pointers to a set of linked URL data  
6 segments forming a complete URL of linked but empty URL components,  
7 the last URL data segment contains the IPA pointer that points to  
8 the IPA in the IPA list used to forward a URL identifier to a  
9 forwarding cache or to that distal web cache storing the requested  
10 web content data corresponding to URL generating the received  
11 sequence of hashing codes. The forwarding table data structure,  
12 including the list of hashing codes, pointers, lists of URL data  
13 segments, and the IPA pointer list enable rapid location of IPAs of  
14 the cooperative forwarding cache or cooperative distal web cache  
15 storing the web content data for a given URL. A received URL can be  
16 quickly hashed for each URL data segment, and used as indices into  
17 the pointers list that in turn points to URL data segments for  
18 determining when a complete string of URL components are linked for  
19 locating the URL in the decomposition tree of the forwarding table.  
20 When a complete string of URL components are linked from a first  
21 component without a parental URL component through and to the last  
22 URL component having an associated IPA pointer, then the complete  
23 URL is determined to be found in the decomposition and is cross  
24 referenced to the IPA then found in the IPA list. When the URL is  
25 located with the associated IPA , then the proximal web cache can  
26 forward the URL or URL identifier to the cooperative web cache  
27 located by the IPA. The URL data segment lists are typically  
28 variable in length and are extended to various adaptive amounts

1 that can change over time depending on the amount of information  
2 within the forwarding table and the quantity of URLs hashed so that  
3 the cooperative cache is an adaptive cooperative cache with a time  
4 variant size of the forwarding table. In the preferred form, the  
5 web content data identifiers include exact URL, wildcard URL or URL  
6 hashing codes that are a sequence of hash codes for respective  
7 concatenated URL segments. In the broad aspect, content data  
8 identifiers are cross referenced in forwarding tables to the source  
9 IPAs of proximal forwarding caches, distal web caches storing  
10 sought after replicated web content or web servers permanently  
11 storing the web content data. Those skilled in the art can make  
12 enhancements, improvements, and modifications to the invention, and  
13 these enhancements, improvements, and modifications may nonetheless  
14 fall within the spirit and scope of the following claims.
